Photosynthesis

Microarray analysis of the CO₂ experiments

3 months

Categories	Gene description	Ratio (elevated/ ambient)
Development	light-induced protein	1,194
Photosynthesis	photosystem II protein K; psbK	1,315
Photosynthesis	Ferredoxin I; chloroplast precursor	1,26
Photosynthesis	photosystem I reaction centre subunit n, chloroplast precursor	1,583
Cell wall metabolism	xyloglucan endo-transglycosylase/ hydrolase	2,582
Photosynthesis	Chlorophyll A-B binding protein	1,508
Stress response	ASR-like	1,735
Lipid, fatty-acid and isoprenoid metabolism	AE9 stearyl-ACP desaturase	3,59
Carbohydrate metabolism	beta-glucosidase isozyme 2 precursor	-2,189
Carbohydrate metabolism	putative glucose-6-phosphate dehydrogenase	-1,232
Protein metabolism	translational initiation factor eIF-4A	-1,606

Ambient

Elevated

30% less transpiration
60% higher WUE

Roots of sugar cane

ASPECT AFTER 3 MONTHS -
Note that the comparison is
between 3 plants from 360ppm
against two plants from
720ppm of CO₂

Productivity

Ambient

Elevated

60% more Biomass

SUGAR & FIBER

	BRIX	Fiber(% FW)	Sucrose (% FW)
Ambient	7.17 ± 0.21	6.62 ± 0.13	2.18 ± 0.20
Elevated	7.75 ± 0.17	7.13 ± 0.21	2.82 ± 0.14*

Speculative calculations

2006 – 386.6 millions of tons
Alcohol – 15.93 millions of m³
Fiber – 25,69 millions of tons

2050 – 649.5 millions of tons
Alcohol 26.76 millions of m³
Fiber - 46.31 millions of tons

Can we use what we have learnt to obtain higher productivity before 2050

CO₂ assimilation and electron transport rate of sugarcane under elevated CO₂

LIGHT REACTIONS

CALVIN CYCLE

CO₂ accelerates light harvesting:
how?
What is the signaling mechanism?

We found that four genes related to light harvesting increase expression under elevated CO₂ and this leads to increase of biomass.

Can we artificially express these genes in chloroplasts and obtain the biomass effect without need of elevation of CO₂ concentration?
